

Entering Docker

This lesson is for the Raspberry Pi 5 and Jetson Nano boards. The Orin board does not require Docker.

Conceptual Understanding:

We refer to the Raspberry Pi/Jetson Nano main environment as the host, and the Docker environment as Docker. Except for the communication agent, which runs on the host, all other programs on the Raspberry Pi/Jetson Nano run within Docker. The host terminal displays the username "jetson/pi," while the Docker username is "root."

1. First Entry into Docker

The Raspberry Pi 5 and Jetson Nano boards will automatically boot into the Docker controller startup program (`run_humble.sh`), and will mount the controller connected to USB into Docker. To ensure the smooth operation of the controller startup program, this Docker container does not mount devices such as the voice module and myserial before starting. Therefore, subsequent programs cannot use this Docker container; a new Docker container with multiple mounted devices needs to be started using a script.

Enter Docker (ensure the voice module and control board are connected to the motherboard/HUB before entering)

```
sh ~/run_humble.sh
```

After entering the Docker terminal, the current directory is `/`. Generally, we need to enter commands in the `/root` directory. Therefore, enter `cd` in the Docker terminal and press Enter to enter the `/root` directory and view files.

Entering the same container from multiple terminals:

Since Docker starts automatically on boot and only has one terminal, it's impossible to enter other commands simultaneously in one terminal. We need to know how to use multiple terminals to run within the same container.

On your Raspberry Pi 5 and Jetson Nano, enter the following command to query information about the container created when you first enter Docker:

```
docker ps
```

CONTAINER ID	IMAGE	COMMAND	CREATED	STATUS	PORTS	NAMES
0f6ed945ea52	192.168.2.51:5000/ros-humble-a1:1.0.0	"/bin/bash"	9 seconds ago	Up 8 seconds		intelligent_sutherland

As shown in the image above, the above content appears, displaying the image as `192.168.2.51:5000/ros-humble-a1:1.0.0`. This corresponds to the image name in our `run_humble.sh`, indicating that this is the container created by executing `sh run_humble.sh`, and its name is `intelligent_sutherland`. The name generated by each user will be different; refer to the actual situation you encounter when querying, as long as the image name matches. We will then use this container name to enter Docker.

Enter the following command on the host machine to enter this container:

```
docker exec -it intelligent_sutherland /bin/bash  
#or  
docker exec -it 0f6ed945ea52 /bin/bash
```

`intelligent_sutherland` or its ID should be modified according to the actual container being created. Press Enter to enter the Docker terminal. This is the terminal we enter when starting the Docker container for the first time. Subsequent program commands need to be entered in the terminal of this Docker container.

2. Non-First Entry

2.1 Entering a Previous Docker Container After a Restart

Sometimes, we modify the code in the Docker container we entered for the first time, and then restart or shut down the machine. If we enter the Docker container using the same method as when we first entered it, we will find that the previous modifications are gone. This is because we restarted a new Docker container, which naturally does not contain our previous modifications. If we need to enter the Docker container again after shutting down the machine, we need to follow these steps: **Query the Docker container name or ID, Restart the Docker container, and then enter the Docker container.**

Enter the following command to query the Docker container you first entered:

```
docker ps -a
```

This will list all containers, including those that are running or not. We determine which container to start based on when we first entered the Docker container. For example, if I started the car Docker container 3 minutes ago, I found that the container's name is `intelligent_sutherland`, and its ID is `0f6ed945ea52`, as shown in the image below:

CONTAINER ID	IMAGE	COMMAND	CREATED	STATUS	PORTS	NAMES
0f6ed945ea52	192.168.2.51:5000/ros-humble:a1:1.0.0	"/bin/bash"	3 minutes ago	Exited (0) 9 seconds ago		intelligent_sutherland
0b14b21aff66	192.168.2.51:5000/ros-humble:5.1.1	"/bin/bash /root/run..."	11 minutes ago	Exited (0) 9 minutes ago		mystifying_ritchie
d0d602729992	192.168.2.51:5000/ros-humble:5.1.1	"/bin/bash /root/run..."	16 minutes ago	Exited (0) 13 minutes ago		strange_ishizaka

Then, enter the following command in the terminal to restart the car Docker container:

```
docker restart intelligent_sutherland  
#or  
docker restart 0f6ed945ea52
```

```
pi@raspberrypi:~ $ docker restart intelligent_sutherland  
intelligent_sutherland  
pi@raspberrypi:~ $
```

`intelligent_sutherland` or the ID should be modified according to the actual container being queried. This command **only needs to be started once after the vehicle restarts**.

Enter the following command in the terminal to enter the vehicle's Docker container:

```
docker exec -it intelligent_sutherland /bin/bash  
#or  
docker exec -it 0f6ed945ea52 /bin/bash
```

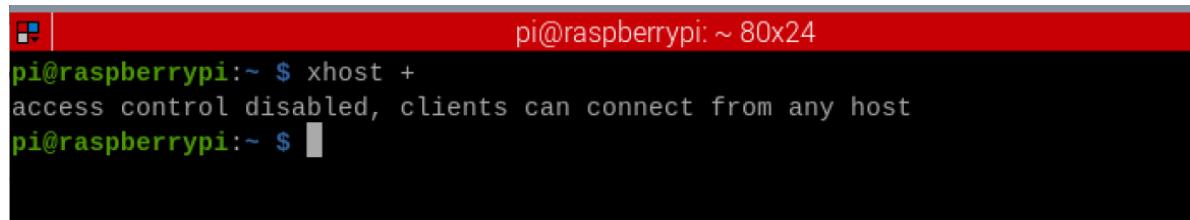

```
File Edit Tabs Help
pi@raspberrypi... x      root@raspb... x
1@raspberrypi:~ $ docker exec -it intelligent_sutherland /bin/bash
-----
OS_DOMAIN_ID: 61 | ROS:
y_robot_type: A1 | my_lidar: tmini | my_camera: nuwa
-----
root@raspberrypi:/#
```

Press Enter to enter the Docker terminal. This is the terminal of the Docker container we enter for the first time. Subsequent program commands need to be entered in the terminal of this Docker container.

If you need to access the terminal after a reboot and the program you're running needs to display a graphical interface, then you need to enter the following command in the vehicle's terminal:

```
xhost +
```

```
pi@raspberrypi:~ $ xhost +
access control disabled, clients can connect from any host
pi@raspberrypi:~ $
```

2.2 Entering a New Docker Container

1. Ensure the existing Docker container is shut down, and run the following command to enable the new container:

```
sh ~/run_humble.sh
```

2. Run the above command to enter the same container program in multiple terminals.
